# Lyapunov exponents for conservative twisting dynamics: a survey

M.-C. ARNAUD <sup>\*†‡</sup>

October 7, 2014

## Abstract

*Finding special orbits (as periodic orbits) of dynamical systems by variational methods and especially by minimization methods is an old method (just think to the geodesic flow). More recently, new results concerning the existence of minimizing sets and minimizing measures were proved in the setting of conservative twisting dynamics. These twisting dynamics include geodesic flows as well as the dynamics close to a completely elliptic periodic point of a symplectic diffeomorphism where the torsion is positive definite (this implies the existence of a normal form  $(\theta, r) \mapsto (\theta + \beta r + o(r), r + o(r))$  with  $\beta$  positive definite). Two aspects of this theory are called the Aubry-Mather theory and the weak KAM theory. They were built by Aubry & Mather in the '80s in the 2-dimensional case and by Mather, Mañé and Fathi in the '90s in higher dimension.*

*We will explain what are the conservative twisting dynamics and summarize the existence results of minimizing measures. Then we will explain more recent results concerning the link between different notions for minimizing measures for twisting dynamics:*

- *their Lyapunov exponents;*
- *their Oseledets splitting;*
- *the shape of the support of the measure.*

*The main question in which we are interested is: given some minimizing measure of a conservative twisting dynamics, is there a link between the geometric shape of its*

# 1 Twisting conservative dynamics

All the dynamics we study here are defined on the cotangent bundle  $T^*M$  of some closed manifold  $M$ , endowed with its usual symplectic form  $\omega$ . More precisely, if  $q = (q_1, \dots, q_n)$  are some coordinates on  $M$ , we complete them with their dual coordinates  $p = (p_1, \dots, p_n)$  to obtain some coordinates on  $T^*M$ : if  $\lambda \in T^*M$  is a 1-form on  $M$ , then

its coordinates  $p_1, \dots, p_n$  are given by  $\lambda = \sum_{i=1}^n p_i dq_i$ . The expression of the symplectic

form in these coordinates is  $\omega = dq \wedge dp = \sum_{i=1}^n dq_i \wedge dp_i$ . A change of coordinates of

$M$  doesn't change the symplectic form  $\omega$  and then the definition is correct. We will generally use the notation  $(q, p)$  for such coordinates.

When  $M = \mathbb{T}^n$ , we will identify  $T^*M$  with the  $2n$ -dimensional annulus  $\mathbb{A}_n = \mathbb{T}^n \times \mathbb{R}^n$ . Let us recall that a diffeomorphism  $f$  of  $T^*M$  is *symplectic* if it preserves the symplectic form:  $f^*\omega = \omega$ .

## 1.1 A local notion: the twist condition

NOTATIONS. We denote by  $\pi : T^*M \rightarrow M$  the canonical projection  $(q, p) \mapsto q$ .

At every  $x = (q, p) \in T^*M$ , we define the vertical subspace  $V(x) = \ker D\pi(x) \subset T_x(T^*M)$  as being the tangent subspace at  $x$  to the fiber  $T_q^*M$ .

**Example 1.** A symplectic  $C^1$  diffeomorphism  $f : \mathbb{A}_1 \rightarrow \mathbb{A}_1$  of the 2-dimensional annulus is a positive symplectic twist map if

- it is homotopic to identity;
- it twists the vertical to the positive side:  $\forall x \in \mathbb{A}_1, D(\pi \circ f)(x) \cdot \begin{pmatrix} 0 \\ 1 \end{pmatrix} > 0$ .

There exists of course a notion of negative symplectic twist map.

The notion of twist map that we introduce is local, but the (local) twist condition implies a global property: when we unfold the cylinder (i.e. we are in the universal covering  $\mathbb{R}^2$  of  $\mathbb{A}_1$  and we consider a lift of the twist map), the image of a fiber  $\{q\} \times \mathbb{R}$  by the lift of a symplectic twist map is then a graph above a part of  $\mathbb{R} \times \{0\}$ :

For example, the map  $f_0 : (q, p) \mapsto (q + p, p)$  is a symplectic twist map of  $\mathbb{A}_1$ .

When thinking to a possible extension of the notion of twisting dynamics to higher dimension, the first possibility is to ask that the image of any vertical  $V(x)$  by the tangent dynamics  $Df$  is transverse to the vertical  $V(f(x))$ . If we express  $Df$  in two charts of coordinates  $(q, p)$ :

$$Df = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

this is equivalent to ask that  $\forall x, \det b(x) \neq 0$ . When  $M = \mathbb{T}^n$ , such diffeomorphisms were introduced and studied by M. Herman in [15], where he called them *monotone*. When  $\dim M \geq 2$ , the monotony condition doesn't imply that the image of a fiber is a graph above the zero section, even if  $M = \mathbb{T}^n$  and if we unfold the  $2n$ -dimensional annulus. For example, the map  $f : \mathbb{A}_2 \rightarrow \mathbb{A}_2$  defined for  $(q, p) \in \mathbb{T}^2 \times \mathbb{R}^2 = \mathbb{C}/(\mathbb{Z} + i\mathbb{Z}) \times \mathbb{R}^2$  by  $f(q, p) = (q + e^{p_1 - ip_2}, p)$  is monotone but the projection of the restriction of its lift to any fiber is not injective.

If  $f$  is a twist map of the 2-dimensional annulus,  $f^2$  is not necessarily a twist map: the twist condition is just valuable for "small times" (here time 1).

Hence for Hamiltonians, we will translate the twist condition for small times. In coordinates  $(q, p)$ , the Hamilton equations for  $H \in C^2(T^*M, \mathbb{R})$  are:

$$\dot{q} = \frac{\partial H}{\partial p}(q, p); \quad \dot{p} = -\frac{\partial H}{\partial q}(q, p).$$

Let us denote the Hamiltonian flow of  $H$  by  $(\varphi_t^H)$  and let  $(\delta q, \delta p)$  be an infinitesimal solution, i.e.  $\begin{pmatrix} \delta q(t) \\ \delta p(t) \end{pmatrix} = D\varphi_t(q(0), p(0)) \cdot \begin{pmatrix} \delta q(0) \\ \delta p(0) \end{pmatrix}$ . By differentiating the Hamilton

equations, we obtain  $\delta\dot{q} = \frac{\partial^2 H}{\partial q \partial p} \delta q + \frac{\partial^2 H}{\partial p^2} \delta p$  and then

$$D(\pi \circ \varphi_t)(q(0), p(0)) \cdot \begin{pmatrix} 0 \\ \delta p \end{pmatrix} = t \frac{\partial^2 H}{\partial p^2}(q(0), p(0)) \delta p + o(t).$$

We will say that the Hamiltonian  $H$  satisfies the twist condition if at every point  $\frac{\partial^2 H}{\partial p^2}$  is non-degenerate. In this case, even for small times, the Hamiltonian flow is not necessarily a twist map; indeed, the  $o(t)$  above is not uniform in  $(q, p)$ .

## 1.2 Global notions: globally positive diffeomorphisms and Tonelli Hamiltonians

Unfortunately, we are able to do nothing with the local definition of twisting dynamics that we gave in the above subsection.

There are two problems:

1. we need to find some special invariant subsets for the dynamics;
2. we want to say something about the Lyapunov exponents along these invariant subsets.

In general there are two main ways to find invariant subsets for those dynamics: perturbative methods and variational methods. Perturbative methods, as K.A.M. theorems are, are valuable close to completely integrable dynamics (see [15] for the definition in the case of the  $2n$ -dimensional annulus). C. Golé gives in [14], section 27.B a similar condition, that he calls “asymptotic linearity”, that makes possible the use of variational methods in this perturbative case. But we won’t explain the perturbative case in this survey. We will only work in the so-called *coercive* case (see section 27.B of [14] for example).

More precisely, we will make some assumptions such that

- we can associate a function  $\mathcal{F}$  to the dynamics, such that the critical points of  $\mathcal{F}$  are in some sense the orbits for the dynamics;
- the function  $\mathcal{F}$  admits some minima, and then some “minimizing orbits”. For the symplectic twist maps of the 2-dimensional annulus, these minimizing orbits are the heart of the theory that S. Aubry and J. Mather independently developed at the beginning of the ’80s (see [6] and [21]).

That is why we introduce the following definitions. The first one comes from [18] and [14], the second one is very classical.

### 1.2.1 Globally positive diffeomorphisms

DEFINITION. A *globally positive* diffeomorphism of  $\mathbb{A}_n$  is a symplectic  $C^1$  diffeomorphism  $f : \mathbb{A}_n \rightarrow \mathbb{A}_n$  that is homotopic to  $\text{Id}_{\mathbb{A}_n}$  and that has a lift  $F : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}^n \times \mathbb{R}^n$  that admits a  $C^2$  generating function  $S : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$  such that:

- $\forall k \in \mathbb{Z}^n, S(q+k, Q+k) = S(q, Q)$ ;
- there exists  $\alpha > 0$  such that:  $\frac{\partial^2 S}{\partial q \partial Q}(q, Q)(v, v) \leq -\alpha \|v\|^2$ ;
- $F$  is implicitly given by:

$$F(q, p) = (Q, P) \iff \begin{cases} p = -\frac{\partial S}{\partial q}(q, Q) \\ P = \frac{\partial S}{\partial Q}(q, Q) \end{cases}$$

**Example 2.** The diffeomorphism  $F_0 : (q, p) \in \mathbb{R}^n \times \mathbb{R}^n \mapsto (q+p, p) \in \mathbb{R}^n \times \mathbb{R}^n$  is the lift of a globally positive diffeomorphism  $f_0$  of  $\mathbb{A}_n$  and a generating function associated to  $F_0$  is defined by  $S_0(q, Q) = \frac{1}{2} \|q - Q\|^2$ .

If  $f, F$  satisfy the above hypotheses, the restriction to any fiber  $\{q\} \times \mathbb{R}^n$  of  $\pi \circ F$  and  $\pi \circ F^{-1}$  are diffeomorphisms (a proof is given in [14]). In particular, this implies that  $f$  is (locally) monotone.

Moreover, for every  $k \geq 2, q_0, q_k \in \mathbb{R}^n$ , the function  $\mathcal{F} : (\mathbb{R}^n)^{k-1} \rightarrow \mathbb{R}$  defined by  $\mathcal{F}(q_1, \dots, q_{k-1}) = \sum_{j=1}^k S(q_{j-1}, q_j)$  has a minimum, and at every critical point for  $\mathcal{F}$ , the following sequence is a piece of orbit for  $F$ :

$$(q_0, -\frac{\partial S}{\partial q}(q_0, q_1)), (q_1, \frac{\partial S}{\partial Q}(q_0, q_1)), (q_2, \frac{\partial S}{\partial Q}(q_1, q_2)), \dots, (q_k, \frac{\partial S}{\partial Q}(q_{k-1}, q_k)).$$

For the map  $F_0$  defined in example 2, the function  $\mathcal{F}_0$  defined by

$\mathcal{F}_0(q_1, \dots, q_{k-1}) = \frac{1}{2} \sum_{j=1}^k \|q_{j-1} - q_j\|^2$  attains its minimum at its unique critical point

$(q_1, \dots, q_{k-1}) = (q_0 + \frac{q_k - q_0}{k}, q_0 + 2\frac{q_k - q_0}{k}, \dots, q_0 + (k-1)\frac{q_k - q_0}{k})$  and the corresponding piece of orbit is:

$$(q_0, \frac{q_k - q_0}{k}), (q_1, \frac{q_k - q_0}{k}), \dots, (q_k, \frac{q_k - q_0}{k}).$$

Let us discuss a little the condition on  $\frac{\partial^2 S}{\partial q \partial Q}$ . If the matrix of  $Df$  in coordinates  $(q, p)$  is  $Df = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ , we have

$$(b(q, p))^{-1} = -\frac{\partial^2 S}{\partial q \partial Q}(q, Q).$$

Hence the condition that we gave for the partial derivatives of  $S$  can be rewritten in terms of matrices:  $b^{-1} + {}^t b^{-1} \geq \alpha \mathbf{1}$  where  $\mathbf{1}$  is the identity matrix and we use the usual order for the symmetric matrices.

The reader could think to some other possible notions of global twist, for which  ${}^t b^{-1} + b^{-1}$  is indefinite. But in this case, very pathological phenomena can occur; M. Herman showed very strange phenomena in the case of a “normal indefinite torsion” in [16] (the torsion is  ${}^t b + b$  and it has the same signature as  ${}^t b^{-1} + b^{-1} = {}^t b^{-1}({}^t b + b)b^{-1}$ ).

### 1.2.2 Tonelli Hamiltonians

A  $C^2$  function  $H : \mathbb{T}^*M \rightarrow \mathbb{R}$  is a *Tonelli Hamiltonian* if it is:

- superlinear in the fiber, i.e.  $\forall A \in \mathbb{R}, \exists B \in \mathbb{R}, \forall (q, p) \in T^*M, \|p\| \geq B \Rightarrow H(q, p) \geq A\|p\|$ ;
- $C^2$ -convex in the fiber i.e. for every  $(q, p) \in T^*M$ , the Hessian  $\frac{\partial^2 H}{\partial p^2}$  of  $H$  in the fiber direction is positive definite as a quadratic form.

We denote the Hamiltonian flow of  $H$  by  $(\varphi_t^H)$  and the Hamiltonian vector-field by  $X_H$ . Note that the flow of a Tonelli Hamiltonian defined on  $\mathbb{A}_n$  is not necessarily a globally positive diffeomorphism. A geodesic flow is an example of a Tonelli flow. For example, the flat metric on  $\mathbb{T}^n$  corresponds to the Tonelli Hamiltonian  $H_0(q, p) = \frac{1}{2}\|p\|^2$  and its time-one flow is nothing but the map  $f_0$  that we defined in example 2.

At the end of the '80s, J. Mather extended Aubry-Mather theory to the Tonelli Hamiltonians, introducing the concept of globally minimizing orbits and minimizing measures (see [22] and [20]).

To explain that, we associate to any Tonelli Hamiltonian  $H : T^*M \rightarrow \mathbb{R}$  its Lagrangian  $L : TM \rightarrow \mathbb{R}$  that is dual to  $H$  via the formula:

$$\forall (q, v) \in TM, L(q, v) = \sup_{p \in T_q^*M} (p.v - H(q, p)).$$

Then  $L$  is as regular as  $H$  is and is superlinear and  $C^2$ -convex in the fiber direction (see for example [11]). Moreover, we have:

$$L(q, v) + H(q, p) = p.v \iff v = \frac{\partial H}{\partial p}(q, p) \iff p = \frac{\partial L}{\partial v}(q, v).$$

If  $\gamma : [\alpha, \beta] \rightarrow M$  is an absolutely continuous arc, its *Lagrangian action* is then:

$$A_L(\gamma) = \int_{\alpha}^{\beta} L(\gamma(t), \dot{\gamma}(t)) dt.$$

## 1.3 Minimizing measures

### 1.3.1 Case of the globally positive diffeomorphisms of the 2-dimensional annulus

We use the notations that were introduced in subsection 1.2.1. In the 2-dimensional case, J. Mather and Aubry & Le Daeron proved in [6] and [21] the existence of orbits  $(q_i, p_i)_{i \in \mathbb{Z}}$  for  $F$  that are *globally minimizing*. This means that for every  $\ell \in \mathbb{Z}$  and every  $k \geq 2$ ,  $(q_{\ell+1}, \dots, q_{\ell+k-1})$  is minimizing the function  $\mathcal{F}$  defined by:

$$\mathcal{F}(q_{\ell+1}, \dots, q_{\ell+k-1}) = \sum_{i=\ell+1}^{\ell+k-1} S(q_{i-1}, q_i).$$

Then each of these orbits  $(q_i, p_i)_{i \in \mathbb{Z}}$  is supported in the graph of a Lipschitz map defined on a closed subset of  $\mathbb{T}$ , and there exists a bi-Lipschitz orientation preserving homeomorphism  $h : \mathbb{T} \rightarrow \mathbb{T}$  such that  $(q_i)_{i \in \mathbb{Z}} = (h^i(q_0))_{i \in \mathbb{Z}}$ . Hence each of these orbits has a *rotation number*.

Moreover, for each rotation number  $\rho \in \mathbb{R}$ , there exists a minimizing orbit that has this rotation number and there even exists a *minimizing measure*, i.e. an invariant measure the support of whose is filled by globally minimizing orbit, such that all the orbits contained in the support have the same rotation number  $\rho$ . These supports are sometimes called *Aubry-Mather set*.

In the following picture that concerns the so-called standard twist map, you can observe some invariant curves, some Cantor subsets and some periodic islands that must contain one periodic point.

Different kinds of Aubry-Mather sets can occur in this setting:

1. some of them are invariant loops that are the graphs of some Lipschitz maps  $\eta : \mathbb{T} \rightarrow \mathbb{R}$ ;
2. some other ones are just periodic orbits;
3. some of these Aubry-Mather sets are Cantor sets.

In the case 1, it can happen that the dynamics restricted to the curve is bi-Lipschitz conjugate to a rotation; in this case the Lyapunov exponents of the invariant measure supported in the curve are zero. This is the case for the KAM curves. But P. Le Calvez proved in [17] that in general (i.e. for a dense and  $G_\delta$  subset of the set of the symplectic twist maps), there exists an open and dense subset  $U$  of  $\mathbb{R}$  such that any Aubry-Mather set that has its rotation number in  $U$  is uniformly hyperbolic.

### 1.3.2 Case of the globally positive diffeomorphisms in higher dimension

For globally positive diffeomorphism in higher dimension, Garibaldi & Thieullen prove the existence of globally minimizing orbits and measures in [13]. The results that they obtain are very similar to the ones that we recall in subsection 1.3.3 for Tonelli Hamiltonians.

REMARKS. There exists too an Aubry-Mather theory for time-one maps of time-dependent Tonelli Hamiltonians (see for example [7]). Even when the manifold  $M$  is  $\mathbb{T}^n$ , the time-one map is not necessarily a globally positive diffeomorphism of  $\mathbb{A}_n$ . Moreover, except for the 2-dimensional annulus (see [23]), it is unknown if a globally positive diffeomorphism is always the time-one map of a time-dependent Tonelli Hamiltonian (see theorem 41.1 in [14] for some partial results). In this survey, we won't speak about these time-one maps.

### 1.3.3 Case of the Tonelli Hamiltonians

It can be proved that if  $q_b, q_e \in M$  are two points of  $M$  and  $\beta > \alpha$  two real numbers, if  $\Gamma(q_b, q_e; \alpha, \beta)$  is the set of the  $C^2$ -arcs  $\gamma : [\alpha, \beta] \rightarrow M$  that join  $q_b$  to  $q_e$  endowed with the  $C^2$ -topology, then  $\gamma$  is a critical point of the restriction of  $A_L$  to  $\Gamma(q_b, q_e; \alpha, \beta)$  if and only if  $\gamma$  is the projection of an arc of orbit for  $H$ . This arc of orbit is then  $(\gamma(t), \frac{\partial L}{\partial v}(\gamma(t), \dot{\gamma}(t)))_{t \in [\alpha, \beta]}$ .

In [22], J. Mather proves the existence of complete orbits  $(\varphi_t^H(q, p))_{t \in \mathbb{R}} = (q(t), p(t))_{t \in \mathbb{R}}$  that are *globally minimizing*, i.e. such that every arc  $(\pi \circ \varphi_t^H(x))_{t \in [\alpha, \beta]} = (q(t))_{t \in [\alpha, \beta]}$  is minimizing for the restriction of  $A_L$  to  $\Gamma(q(\alpha), q(\beta); \alpha, \beta)$ . He proves too the existence of *minimizing measures*, i.e. invariant measures the support of whose is filled by globally minimizing orbit.

When replacing  $L$  by  $L + \lambda$  where  $\lambda$  is any closed 1-form on  $M$ , we obtain the same critical points for the Lagrangian action  $A_{L+\lambda}$  as for the Lagrangian action  $A_L$ . But the minima for those two functions are not the same. Hence, adding different closed 1-form  $\lambda$  to  $L$  is a way to find other invariant measures supported in graphs, these measures being minimizing for  $L + \lambda$ . The supports of these measures are the generalization of the Aubry-Mather sets. A rotation number can be associated to any minimizing measure (see [22]) and it can be proved that there exists a minimizing measure for any rotation number. But this doesn't give the existence of minimizing orbits of any rotation number (indeed the considered measures have not to be ergodic).

## 2 Lyapunov exponents for the minimizing measures and angle of the Oseledets splitting

Here we are interested in the Lyapunov exponents of the minimizing measures for globally positive diffeomorphisms or Tonelli Hamiltonian flows. In the case of symplectic twist maps, we noticed at the end of subsection 1.3.1 that these exponents may be non-zero or zero.

### 2.1 Some simple remarks for Dirac masses

Before looking at the Lyapunov exponents of any invariant measure, let us have a look to what happens for a Dirac mass in dimension 2.

More precisely, let us assume that  $x$  is a fixed point of a 2-dimensional diffeomorphism. We assume that  $\sup\{\|Df(x)\|, \|(Df(x))^{-1}\|\} \leq C$  where  $C$  is some constant. Let  $\lambda_1, \lambda_2$  be the two (complex) eigenvalues for  $Df(x)$ ; then the Lyapunov exponents for the Dirac mass  $\delta_x$  are  $\log(|\lambda_1|)$  and  $\log(|\lambda_2|)$ . Let us assume that  $\lambda_1$  and  $\lambda_2$  are real and let us denote by  $E_1, E_2$  the corresponding eigenspaces.

#### 2.1.1 What happens when the stable and unstable subspaces are close together

We have

**Simple principle:** *if the eigenspaces  $E_1$  and  $E_2$  are close together, then the two eigenvalues  $\lambda_1$  and  $\lambda_2$  have to be close together too.*

*More precisely, if  $e_i$  is a unitary vector on  $E_i$ , we have:*

$$|\lambda_1 - \lambda_2| \leq 2C \sup\left\{ \frac{\|e_2 - e_1\|}{\|e_1 + e_2\|}, \frac{\|e_1 + e_2\|}{\|e_1 - e_2\|} \right\}.$$

**Proof of the simple principle.** We just compute

$$Df(x) \cdot \frac{e_2 - e_1}{\|e_2 - e_1\|} = \frac{\lambda_2 + \lambda_1}{2} \cdot \frac{e_2 - e_1}{\|e_2 - e_1\|} + \frac{\lambda_2 - \lambda_1}{2} \frac{e_2 + e_1}{\|e_2 - e_1\|}.$$

As  $e_2 - e_1$  and  $e_1 + e_2$  are orthogonal, we deduce

$$\frac{|\lambda_2 - \lambda_1| \|e_2 + e_1\|}{2 \|e_2 - e_1\|} \leq \left\| Df(x) \cdot \frac{e_2 - e_1}{\|e_2 - e_1\|} \right\| \leq \|Df(x)\| \leq C.$$

Changing  $e_1$  into  $-e_1$ , we obtain the second inequality.  $\square$

If  $f$  is symplectic, we have  $\lambda_2 = \frac{1}{\lambda_1}$ . In this case, if the eigenspaces are close together, the two eigenvalues have to be close to 1 and then the Lyapunov exponents are close to 0.

This simple remark for fixed point can be generalized to any dimension and any invariant measure in the following way. For a proof, see [4].

**Proposition 1.** *Let  $K$  be a compact subset of a manifold  $N$ , let  $C > 0$  be a real number. Then, for any  $f \in \text{Diff}^1(M)$  so that  $\max\{\|Df|_K\|, \|Df|_K^{-1}\|\} \leq C$ , if  $f$  has an invariant ergodic measure  $\mu$  with support in  $K$  such that the Oseledets stable and unstable bundles  $E^s$  and  $E^u$  of  $\mu$  have the same dimension  $d$ , if we denote by  $\Lambda_u$  the sum of the positive Lyapunov exponents and by  $\Lambda_s$  the sum of the negative Lyapunov exponents, then:*

$$0 < \Lambda_u - \Lambda_s \leq d \log \left( 1 + (C^2 + 1) \int \text{dist}(E^u, E^s) d\mu \right)$$

where  $\text{dist}$  is the distance.

If for example  $f$  is a symplectic diffeomorphism of  $T^*M$ , then  $E^u$  and  $E^s$  have same dimension (see for example [9]). We deduce from the above proposition that if the stable and unstable Oseledets bundles are close together, then all the Lyapunov exponents are close to 0. This result is not very surprising and not specific to the twisting dynamics. What is more surprising and specific to the twisting dynamics will come in the next section.

### 2.1.2 What happens when the stable and unstable subspaces are far from each other

For general symplectic dynamics, we can have simultaneously two eigenvalues that are close together and two eigenspaces that are not close together. See for example the linear isomorphism of  $\mathbb{R}^2$  with matrix in the usual basis:

$$M = \begin{pmatrix} 1 + \varepsilon & 0 \\ 0 & \frac{1}{1 + \varepsilon} \end{pmatrix}$$

with  $\varepsilon > 0$  small enough.

As noticed by J.-C. Yoccoz, this cannot happen for the minimizing Dirac masses of a twist map of the 2-dimensional annulus. It can be proved that at the fixed point  $x$  corresponding to such a minimizing Dirac mass  $\delta_x$ , the eigenvalues of  $Df(x)$  are real. We denote them by  $\lambda_1, \lambda_2$  and by  $E_1, E_2$  the two corresponding eigenspaces and by  $M = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$  the matrix of  $Df(x)$  in coordinates  $(q, p)$ . Then we have

**Simple result** *If the torsion  $b$  is bounded from below by a positive number, if  $E_1$  and  $E_2$  are far from each other, then  $|\lambda_2 - \lambda_1|$  cannot be too small. More precisely, if  $\alpha$  is the angle between  $E_1$  and  $E_2$ , then we have*

$$|b| \leq \sup\{1, (\cotan(\alpha))^2\} |\lambda_2 - \lambda_1|.$$

**Proof of the simple result.** The angle between  $E_1$  and  $E_2$  being  $\alpha$ , there exists a matrix  $R$  of rotation such that if  $P := R \begin{pmatrix} 1 & \cotan\alpha \\ 0 & 1 \end{pmatrix}$ , then  $P \begin{pmatrix} 1 \\ 0 \end{pmatrix} = e_1$  and  $P \begin{pmatrix} 0 \\ 1 \end{pmatrix} = e_2$ . As  $R$  is a matrix of rotation, the modulus of all the coefficients of  $P = \begin{pmatrix} \alpha & \beta \\ \delta & \gamma \end{pmatrix}$  is less than  $\sup\{1, |\cotan\alpha|\}$ . Moreover, we have:

$$M = \begin{pmatrix} \gamma & -\beta \\ -\delta & \alpha \end{pmatrix} \cdot \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} \cdot \begin{pmatrix} \alpha & \beta \\ \delta & \gamma \end{pmatrix} = \begin{pmatrix} * & \delta \cdot \gamma (\lambda_1 - \lambda_2) \\ * & * \end{pmatrix}.$$

We deduce that  $b = \delta\beta(\lambda_1 - \lambda_2)$  and the wanted result. □

## 2.2 Number of non-zero Lyapunov exponents

Before giving an estimation of the non-zero Lyapunov exponents, we will try to find how many they are. As the dynamics is symplectic, we know that the number of negative Lyapunov exponents is equal to the number of positive Lyapunov exponents and then the number of zero Lyapunov exponents is even (see [9] for a proof).

### 2.2.1 The two Green bundles

The Green bundles are two Lagrangian bundles that are defined along the minimizing orbits. In general, they are measurable but not continuous. Let us recall that a subspace  $H$  of the symplectic space  $T_x(T^*M)$  is Lagrangian if its dimension is  $n$  and if the restriction of the symplectic form to  $H$  vanishes:  $\omega|_{H \times H} = 0$ .

The Green bundles were introduced in the '50s by L. W. Green to give a proof of the 2-dimensional version of Hopf conjecture: a Riemannian metric of  $\mathbb{T}^n$  with no conjugate

points is flat. Then P. Foulon extended the construction to the Finsler metrics in [12] and G. Contreras & R. Iturriaga built them for any Tonelli Hamiltonian in [10]. The construction for the twist maps of the annulus, and more generally for the twist maps of  $\mathbb{T}^n \times \mathbb{R}^n$  is due to M. Bialy & R. MacKay (see [8]).

We will recall here their precise definition and we will give their main properties. Before this, let us recall that there exists a way to compare different Lagrangian subspaces of  $T_x(T^*M)$  that are transverse to the vertical  $V(x)$ . We choose some coordinates  $(q, p)$  as explained at the beginning of section 1 and we denote the linearized coordinates by  $(\delta q, \delta p)$  of  $T_x(T^*M)$ . If  $H_1, H_2$  are two Lagrangian subspaces of  $T_x(T^*M)$  that are transverse to the vertical  $V(x)$ , we can write them in coordinates  $(\delta q, \delta p)$  as the graph of some symmetric matrices  $S_1, S_2$ . We say that  $L_1$  is under  $L_2$  and write  $L_1 \leq L_2$  when  $S_2 - S_1$  is a positive semi-definite matrix. We say that  $L_1$  is strictly under  $L_2$  and write  $L_1 < L_2$  if  $L_1 \leq L_2$  and  $L_1$  and  $L_2$  are transverse. This is equivalent to say that  $S_2 - S_1$  is positive definite. It can be proved that this definition doesn't depend on the chart that we choose. For an equivalent but more intrinsic definition, see [1]. We begin by recalling some properties of the Green bundles.

Along every minimizing orbit of a globally positive diffeomorphism  $F : \mathbb{T}^n \times \mathbb{R}^n \rightarrow \mathbb{T}^n \times \mathbb{R}^n$  or a Tonelli Hamiltonian flow  $H : T^*M \rightarrow \mathbb{R}$  that we will denote by  $(\mathcal{D}_t)$  (with  $t$  in  $\mathbb{Z}$  or  $\mathbb{R}$ ), we can define two Lagrangian bundles  $G_-$  and  $G_+$  that satisfy the following properties.

- they are transverse to the vertical and  $G_- \leq G_+$ ;
- $G_-$  and  $G_+$  are invariant by the linearized dynamics, i.e.  $D\mathcal{D}_t.G_{\pm} = G_{\pm} \circ \mathcal{D}_t$ ;
- for every compact  $K$  such that the orbit of every point of  $K$  is minimizing, the two Green bundles restricted to  $K$  are uniformly far from the vertical;
- (dynamical criterion) if the orbit of  $x$  is minimizing and relatively compact in  $T^*M$ , if  $\liminf_{t \rightarrow +\infty} \|D(\pi \circ \mathcal{D}_t)(x)v\| \leq +\infty$  then  $v \in G_-(x)$ .  
If  $\liminf_{t \rightarrow +\infty} \|D(\pi \circ \mathcal{D}_{-t})(x)v\| \leq +\infty$  then  $v \in G_+(x)$ .

The bundles  $G_-$  and  $G_+$  are the *Green bundles*. The proof of the results that we mentioned before can be found in [1] for the Tonelli Hamiltonians and in [4] for the globally positive diffeomorphisms.

An easy consequence of the dynamical criterion and the fact that the Green bundles are Lagrangian is that when there is a splitting of  $T_x(T^*M)$  into the sum of a stable, a center and an unstable bundles  $T_x(T^*M) = E^s(x) \oplus E^c(x) \oplus E^u(x)$ , for example an Oseledec's splitting or a partially hyperbolic splitting, then we have

$$E^s \subset G_- \subset E^s \oplus E^c \quad \text{and} \quad E^u \subset G_+ \subset E^u \oplus E^c.$$

Let us give the argument of the proof. Because of the dynamical criterion, we have  $E^s \subset G_-$ . Because the dynamical system is symplectic, the symplectic orthogonal subspace to  $E^s$  is  $(E^s)^\perp = E^s \oplus E^c$  (see e.g. [9]). Because  $G_-$  is Lagrangian, we have  $G_-^\perp = G_-$ . We obtain then  $G_-^\perp = G_- \subset E^{s\perp} = E^s \oplus E^c$ .

Let us note the following straightforward consequence: for a minimizing measure, the whole information concerning the positive (resp. negative) Lyapunov exponents is contained in the restricted linearized dynamics  $DD_t|_{G_+}$  (resp.  $DD_t|_{G_-}$ ). In particular, when the measure is weakly hyperbolic, we have almost everywhere  $G_+ = E^u$  and  $G_- = E^s$ .

We now give the precise definition of the two Green bundles.

**DEFINITION.** If the orbit of  $x$  is minimizing, then the family  $(DD_t.V(\mathcal{D}_{-t}x))_{t>0}$  is a decreasing family of Lagrangian subspaces that converges to  $G_+(x)$  and the family  $(DD_{-t}.V(\mathcal{D}_tx))_{t>0}$  is an increasing family of Lagrangian subspaces that converges to  $G_-(x)$ .

### 2.2.2 Link between the central dimension and the dimension of $G_- \cap G_+$

From  $E^s \subset G_- \subset E^s \oplus E^c$  and  $E^u \subset G_+ \subset E^u \oplus E^c$ , we deduce that  $G_- \cap G_+ \subset E^c$ . Hence  $G_- \cap G_+$  is an isotropic subspace (for  $\omega$ ) of the symplectic space  $E^c$ . We deduce that  $\dim(E^c) \geq 2 \dim(G_- \cap G_+)$ . When  $E^s \oplus E^c \oplus E^u$  designates the Oseledets splitting of some minimizing measure  $\mu$ , what is proved in [3] is that this inequality is an equality  $\mu$  almost everywhere for the Tonelli Hamiltonian flows and the same result is proved for the globally positive diffeomorphisms in [5].

**Theorem 1.** *Let  $(\mathcal{D}_t)$  (with  $t$  in  $\mathbb{Z}$  or  $\mathbb{R}$ ) be a globally positive diffeomorphism or a Tonelli Hamiltonian flow. Let  $\mu$  be a minimizing measure and let us denote by  $p$  the  $\mu$ -almost everywhere dimension of  $G_- \cap G_+$ . Then  $\mu$  has exactly  $2p$  zero Lyapunov exponents,  $n - p$  positive Lyapunov exponents and  $n - p$  negative Lyapunov exponents.*

The idea is the following one. Firstly, let us notice that we have nothing to prove when  $\dim(G_- \cap G_+) = n$  because we know that  $\dim(E^c) \geq 2 \dim(G_- \cap G_+) = 2n$ ; in this case,  $\dim(E^c) = 2n$  and all the Lyapunov exponents are zero.

In the other case, we consider the following restricted-reduced linearized dynamics. Let  $\mu$  be an ergodic minimizing measure. Then the quantity  $\dim(G_- \cap G_+)$  is  $\mu$ -almost everywhere constant. We denote this dimension by  $p$  and we assume that  $p < n$ .

**NOTATIONS.** We introduce the following linear spaces (see [3]):  $E = G_- + G_+$ ,  $R = G_- \cap G_+$ ,  $F$  is the reduced space  $F = E/R$ . As  $E$  is coisotropic for  $\omega$  with  $E^{\perp\omega} = R$ , then  $F$  is the symplectic reduction of  $E$ . As  $E$  and  $R$  are invariant by the linearized dynamics, then we can define a cocycle  $M_t$  on  $F$  as the reduced linearized dynamics. This cocycle is then symplectic for the reduced symplectic form  $\Omega$ .

In [3] and [5], we define for the cocycle  $(M_t)$  a vertical subspace, some reduced Green bundles  $g_-$  and  $g_+$  that has properties similar to the ones of  $G_{\pm}$ , and we prove that  $g_-$  and  $g_+$  are transverse  $\mu$ -almost everywhere. As we will explain in next subsection, the transversality of the Green bundles implies the (weak) hyperbolicity of the measure. Here we have only the transversality of the reduced Green bundles, but this imply that the cocycle  $(M_t)$  is (weakly) hyperbolic and then that the linearized dynamics has at least  $2(n - p)$  non-zero Lyapunov exponents. This gives the conclusion.

### 2.2.3 The transversality of the two Green bundles implies some hyperbolicity

We will explain here why a minimizing measure  $\mu$  is weakly hyperbolic when the Green bundles are transverse almost everywhere. We will deal with the discrete case (i.e. globally positive diffeomorphisms of  $\mathbb{A}_n$ ). The diffeomorphism is denoted by  $f$  and we assume that  $\mu$ -almost everywhere we have:  $T_x\mathbb{A}_n = G_-(x) \oplus G_+(x)$ . We want to prove that  $f$  has at least  $n$  positive Lyapunov exponents; in this case, because  $f$  is symplectic,  $\mu$  has also  $n$  negative Lyapunov exponents (see [9]).

The idea is to use a bounded (but non continuous) symplectic change of linearized coordinates along the minimizing orbits where  $T_x\mathbb{A}_n = G_-(x) \oplus G_+(x)$  such that  $G_+$  becomes the horizontal. Because  $G_+$  is invariant by  $Df$ , the symplectic matrix of  $Df^k$  is:  $M^k(x) = \begin{pmatrix} a_k(x) & b_k(x) \\ 0 & d_k(x) \end{pmatrix}$ .

NOTATIONS. For  $k \in \mathbb{Z}$ , we use the notation  $G_k(x) = Df^k V(f^{-k}x)$ . Then we know that  $(G_k(x))_{k \geq 1}$  is a decreasing sequence of Lagrangian subspaces that converges to  $G_+(x)$  and that  $(G_{-k}(x))_{k \geq 1}$  is an increasing sequence of Lagrangian subspaces that converges to  $G_-(x)$ .

In the symplectic coordinates that we choose,  $G_k$  is the graph of a symmetric matrix  $s_k$ .

Because  $G_k$  is transverse to the vertical, we have  $\det b_k \neq 0$ . Because of the definition of  $G_k$ , we have then  $d_k(x) = s_k(f^k x) b_k(x)$ . As  $s_k(x)_{k \geq 1}$  is decreasing and tends to  $\mathbf{0}$  (because the horizontal is  $G_+$ ), the symmetric matrix  $s_k(f^k x)$  is positive definite. Moreover, because the matrix  $M^k(x)$  is symplectic, we have:

$$\left(M^k(x)\right)^{-1} = \begin{pmatrix} {}^t d_k(x) & -{}^t b_k(x) \\ 0 & {}^t a_k(x) \end{pmatrix}$$

and by definition of  $g_{-k}(x)$ :  ${}^t a_k(x) = -s_{-k}(x) {}^t b_k(x)$  and finally:

$$M^k(x) = \begin{pmatrix} -b_k(x) s_{-k}(x) & b_k(x) \\ 0 & s_k(f^k x) b_k(x) \end{pmatrix}.$$

The proof is then made of several lemmata. The first one is a consequence of Egorov theorem and of the fact that  $\mu$ -almost everywhere on  $\text{supp}\mu$ ,  $G_+$  and  $G_-$  are transverse and then  $-s_-$  is positive definite.

**Lemma 1.** *For every  $\varepsilon > 0$ , there exists a measurable subset  $J_\varepsilon$  of  $\text{supp}\mu$  such that:*

- $\mu(J_\varepsilon) \geq 1 - \varepsilon$ ;
- on  $J_\varepsilon$ ,  $(s_k)_{k \geq 1}$  and  $(s_{-k})_{k \geq 1}$  converge uniformly ;
- there exists two constants  $\beta = \beta(\varepsilon) > \alpha = \alpha(\varepsilon) > 0$  such that:  $\forall x \in J_\varepsilon, \beta \mathbf{1} \geq -s_-(x) \geq \alpha \mathbf{1}$  where  $g_-$  is the graph of  $s_-$ .

We deduce:

**Lemma 2.** *Let  $J_\varepsilon$  be as in the previous lemma. On the set  $\{(k, x) \in \mathbb{N} \times J_\varepsilon, f^k(x) \in J_\varepsilon\}$ , the sequence of conorms  $(m(b_k(x)))$  converge uniformly to  $+\infty$ , where  $m(b_k) = \|b_k^{-1}\|^{-1}$ .*

PROOF Let  $k, x$  be as in the lemma.

The matrix  $M_k(x) = \begin{pmatrix} -b_k(x)s_{-k}(x) & b_k(x) \\ 0 & s_k(f^k x)b_k(x) \end{pmatrix}$  being symplectic, we have:

$-s_{-k}(x)^t b_k(x) s_k(f^k x) b_k(x) = \mathbf{1}$  and thus  $-b_k(x) s_{-k}(x)^t b_k(x) s_k(f^k x) = \mathbf{1}$  and:

$$b_k(x) s_{-k}(x)^t b_k(x) = - (s_k(f^k x))^{-1}.$$

We know that on  $J_\varepsilon$ ,  $(s_k)$  converges uniformly to zero. Hence, for every  $\delta > 0$ , there exists  $N = N(\delta)$  such that:  $k \geq N \Rightarrow \|s_k(f^k x)\| \leq \delta$ . Moreover, we know that  $\|s_{-k}(x)\| \leq \beta$ . Hence, if we choose  $\delta' = \frac{\delta^2}{\beta}$ , for every  $k \geq N = N(\delta')$  and  $x \in J_\varepsilon$  such that  $f^k x \in J_\varepsilon$ , we obtain:

$$\forall v \in \mathbb{R}^p, \beta \|{}^t b_k(x) v\|^2 = {}^t v b_k(x) (\beta \mathbf{1}) {}^t b_k(x) v \geq -{}^t v b_k(x) s_{-k}(x) {}^t b_k(x) v = {}^t v (s_k(f^k x))^{-1} v$$

and we have:  ${}^t v (s_k(f^k x))^{-1} v \geq \frac{\beta}{\delta^2} \|v\|^2$  because  $s_k(f^k x)$  is a positive definite matrix that is less than  $\frac{\delta^2}{\beta} \mathbf{1}$ . We finally obtain:  $\|{}^t b_k(x) v\| \geq \frac{1}{\delta} \|v\|$  and then the result that we wanted.  $\square$

From now we fix a small constant  $\varepsilon > 0$ , associate a set  $J_\varepsilon$  with  $\varepsilon$  via lemma 1 and two constants  $0 < \alpha < \beta$ ; then there exists  $N \geq 0$  such that

$$\forall x \in J_\varepsilon, \forall k \geq N, f^k(x) \in J_\varepsilon \Rightarrow m(b_k(x)) \geq \frac{2}{\alpha}.$$

**Lemma 3.** *Let  $J_\varepsilon$  be as in lemma 1. For  $\mu$ -almost point  $x$  in  $J_\varepsilon$ , there exists a sequence of integers  $(j_k) = (j_k(x))$  tending to  $+\infty$  such that:*

$$\forall k \in \mathbb{N}, m(b_{j_k}(x) s_{-j_k}(x)) \geq \left(2^{\frac{1-\varepsilon}{2N}}\right)^{j_k}.$$

PROOF As  $\mu$  is ergodic for  $f$ , we deduce from Birkhoff ergodic theorem that for almost every point  $x \in J_\varepsilon$ , we have:

$$\lim_{\ell \rightarrow +\infty} \frac{1}{\ell} \#\{0 \leq k \leq \ell - 1; f^k(x) \in J_\varepsilon\} = \mu(J_\varepsilon) \geq 1 - \varepsilon.$$

We introduce the notation:  $N(\ell) = \#\{0 \leq k \leq \ell - 1; f^k(x) \in J_\varepsilon\}$ .  
For such an  $x$  and every  $\ell \in \mathbb{N}$ , we find a number  $n(\ell)$  of integers:

$$0 = k_1 \leq k_1 + N \leq k_2 \leq k_2 + N \leq k_3 \leq k_3 + N \leq \dots \leq k_{n(\ell)} \leq \ell$$

such that  $f^{k_i}(x) \in J_\varepsilon$  and  $n(\ell) \geq \lfloor \frac{N(\ell)}{N} \rfloor \geq \frac{N(\ell)}{N} - 1$ . In particular, we have:  $\frac{n(\ell)}{\ell} \geq \frac{1}{N}(\frac{N(\ell)}{\ell} - \frac{N}{\ell})$ , the right term converging to  $\frac{\mu(J_\varepsilon)}{N} \geq \frac{1-\varepsilon}{N}$  when  $\ell$  tends to  $+\infty$ . Hence, for  $\ell$  large enough, we find:  $n(\ell) \geq 1 + \ell \frac{1-\varepsilon}{2N}$ .

As  $f^{k_i}(x) \in J_\varepsilon$  and  $k_{i+1} - k_i \geq N$ , we have:  $m(b_{k_{i+1}-k_i}(f^{k_i}(x))) \geq \frac{2}{\alpha}$ . Moreover, we have:  $m(s_{-(k_{i+1}-k_i)}(f^{k_i}(x))) \geq \alpha$ ; hence:

$$m(b_{k_{i+1}-k_i}(f^{k_i}(x))s_{-(k_{i+1}-k_i)}(f^{k_i}(x))) \geq 2.$$

But the matrix  $-b_{k_{n(\ell)}}(x)s_{-k(n(\ell))}(x)$  is the product of  $n(\ell) - 1$  such matrix. Hence:

$$m(b_{k_{n(\ell)}}(x)s_{-k(n(\ell))}(x)) \geq 2^{n(\ell)-1} \geq 2^{\ell \frac{1-\varepsilon}{2N}} \geq \left(2^{\frac{1-\varepsilon}{2N}}\right)^{k_{n(\ell)}}.$$

□

This implies that all the Lyapunov exponents of the restriction of  $Df$  to  $G_+$  are greater than  $\log\left(2^{\frac{1-\varepsilon}{2N}}\right) > 0$ .

### 2.3 Lower bounds for the positive Lyapunov exponents

Using a Riemannian metric on  $M$ , we define the horizontal subspace  $\mathcal{H}$  as the kernel of the connection map. Then, for every Lagrangian subspace  $\mathcal{G}$  of  $T_x(T^*M)$ , there exists a linear map  $G : \mathcal{H}(x) \rightarrow V(x)$  whose graph is  $\mathcal{G}$ . That is the meaning of *graph* in what follows. When  $M = \mathbb{T}^n$ , we choose of course  $\mathcal{H} = \mathbb{R}^n \times \{0\}$ .

NOTATIONS. We denote by  $\mathbb{U}$  (resp.  $\mathbb{S}$ ) the linear map  $\mathcal{H} \rightarrow V$  with graph  $G_+$  (resp.  $G_-$ ). When we use symplectic coordinates, their matrices are symmetric.

Along a minimizing orbit in the case of a globally positive diffeomorphism,  $G_k = Df^k(V \circ f^{-k})$  (resp.  $G_{-k} = Df^{-k}(V \circ f^k)$ ) is the graph of  $S_k$  (resp.  $S_{-k}$ ).

Let  $(\mathcal{D}_t)$  (with  $t$  in  $\mathbb{Z}$  or  $\mathbb{R}$ ) be a globally positive dynamics or a Tonelli Hamiltonian flow. Let  $\mu$  be an ergodic minimizing measure. A general fact for ergodic measures and  $C^1$ -bounded dynamics is that the closer the stable and unstable bundles are, the closer to zero the Lyapunov exponents are (see proposition 1 for a more precise statement and [4] for a proof). But in general, the converse assertion is false. We will see that it is true in the case of a twisting dynamics. Let us introduce some notations:

NOTATIONS. For a positive semi-definite symmetric matrix  $S$  that is not the zero matrix, we denote by  $q_+(S)$  its smallest positive eigenvalue.

**Theorem 2.** *Let  $\mu$  be an ergodic minimizing measure of a globally positive diffeomorphism of  $\mathbb{A}_n$  that has at least one non-zero Lyapunov exponent. We denote the smallest positive Lyapunov exponent of  $\mu$  by  $\lambda(\mu)$  and an upper bound for  $\|S_1 - S_{-1}\|$  above  $\text{supp}\mu$  by  $C$ . Then we have:*

$$\lambda(\mu) \geq \frac{1}{2} \int \log \left( 1 + \frac{1}{C} q_+(\mathbb{U} - \mathbb{S})(x) \right) d\mu(x).$$

The proof of this result is given in [5]. There is a similar result for Tonelli Hamiltonians:

**Theorem 3.** *Let  $\mu$  be an ergodic measure minimizing for a Tonelli Hamiltonian  $H : T^*M \rightarrow \mathbb{R}$  and with at least one non zero Lyapunov exponent; then its smallest positive Lyapunov exponent  $\lambda(\mu)$  satisfies:  $\lambda(\mu) \geq \frac{1}{2} \int m(\frac{\partial^2 H}{\partial p^2}) \cdot q_+(\mathbb{U} - \mathbb{S}) d\mu$ .*

The proof of theorem 2 is a little long and involves some technical changes of basis. We prefer to give the proof of theorem 3, that is simpler and shorter. The first point is an easy-to-prove lemma:

**Lemma 4.** *Let  $H : T^*M \rightarrow \mathbb{R}$  be a Tonelli Hamiltonian. Let  $(x_t)$  be a minimizing orbit and let  $U$  and  $S$  be two Lagrangian bundles along this orbit that are invariant by the linearized Hamilton flow and transverse to the vertical. Let  $\delta x_U \in U$  be an infinitesimal orbit contained in the bundle  $U$  and let us denote by  $\delta x_S$  the unique vector of  $S$  such that  $\delta x_U - \delta x_S \in V$  (hence  $\delta x_S$  is not an infinitesimal orbit). Then:*

$$\frac{d}{dt}(\omega(x_t)(\delta x_S(t), \delta x_U(t))) = (\delta x_U(t) - \delta x_S(t)) H_{pp}(x_t) (\delta x_U(t) - \delta x_S(t)) \geq 0.$$

Let  $\mu$  be an ergodic Borel probability measure minimizing for a Tonelli Hamiltonian  $H : T^*M \rightarrow \mathbb{R}$  and with at least one non zero Lyapunov exponent; its support  $K$  is compact and then, there exists a constant  $C > 0$  such that  $\mathbb{U}$  and  $\mathbb{S}$  are bounded by  $C$  above  $K$ . We choose a point  $(q, p)$  that is generic for  $\mu$  and  $(\delta q, \mathbb{U}\delta q)$  in the Oseledets

bundle corresponding to the smallest positive Lyapunov exponent  $\lambda(\mu)$  of  $\mu$ . Using the linearized Hamilton equations (see lemma 4), we obtain:

$$\frac{d}{dt}((\delta q(\mathbb{U} - \mathbb{S})\delta q) = \delta q(\mathbb{U} - \mathbb{S})\frac{\partial^2 H}{\partial p^2}(q_t, p_t)(\mathbb{U} - \mathbb{S})\delta q.$$

Let us notice that  $(\mathbb{U} - \mathbb{S})^{\frac{1}{2}}\delta q$  is contained in the orthogonal space to the kernel of  $\mathbb{U} - \mathbb{S}$ . Hence:

$$\frac{d}{dt}((\delta q(\mathbb{U} - \mathbb{S})\delta q) \geq m\left(\frac{\partial^2 H}{\partial p^2}\right)_{q_+}(\mathbb{U} - \mathbb{S})\delta q(\mathbb{U} - \mathbb{S})\delta q.$$

Moreover  $\delta q \notin \ker(\mathbb{U} - \mathbb{S})$  because  $(\delta q, \mathbb{U}\delta q)$  corresponds to a positive Lyapunov exponent and then  $(\delta q, \mathbb{U}\delta q) \notin G_- \cap G_+$ . Then :

$$\begin{aligned} \frac{2}{T} \log(\|\delta q(T)\|) + \frac{\log 2C}{T} &\geq \frac{1}{T} \log(\delta q(T)(\mathbb{U} - \mathbb{S})(q_T, p_T)\delta q(T)) \geq \\ &\frac{1}{T} \log(\delta q(0)(\mathbb{U} - \mathbb{S})(q, p)\delta q(0)) + \frac{1}{T} \int_0^T m\left(\frac{\partial^2 H}{\partial p^2}\right)_{q_+}((\mathbb{U} - \mathbb{S})(q_t, p_t))dt. \end{aligned}$$

Using Birkhoff's ergodic theorem, we obtain:

$$\lim_{T \rightarrow +\infty} \frac{1}{T} \log(\|\delta q(T)\|) = \lambda(\mu) \geq \frac{1}{2} \int m\left(\frac{\partial^2 H}{\partial p^2}\right)_{q_+}(\mathbb{U} - \mathbb{S})d\mu.$$

## 3 Shape of the support of the minimizing measures and Lyapunov exponents

### 3.1 Some notations and definitions

For any subset  $A \neq \emptyset$  of a manifold  $M$  and any point  $a \in A$ , different kinds of subsets of  $T_a M$  can be defined, that are cones and also a generalizations of the notion of tangent space to a submanifold. We introduce them here when  $M = \mathbb{R}^n$ , but by using some charts, the definition can be extended to any manifold.

DEFINITION. Let  $A \subset \mathbb{R}^n$  a non-empty subset of  $\mathbb{R}^n$  and let  $a \in A$  be a point of  $A$ . Then

- the *contingent cone* to  $A$  at  $a$  is defined as being the set of all the limit points of the sequences  $t_k(a_k - a)$  where  $(t_k)$  is a sequence of real numbers and  $(a_k)$  is a sequence of elements of  $A$  that converges to  $a$ . This cone is denoted by  $C_a A$  and it is a subset of  $T_a \mathbb{R}^n$ ;
- the *limit contingent cone* to  $A$  at  $a$  is the set of the limit points of sequences  $v_k \in C_{a_k} A$  where  $(a_k)$  is any sequence of points of  $A$  that converges to  $a$ . It is denoted by  $\tilde{C}_a A$  and it is a subset of  $T_a \mathbb{R}^n$ ;

- the *paratangent cone* to  $A$  at  $a$  is the set of the limit points of the sequences

$$\lim_{k \rightarrow \infty} t_k(x_k - y_k)$$

where  $(x_k)$  and  $(y_k)$  are sequences of elements of  $A$  converging to  $a$  and  $(t_k)$  is a sequence of elements of  $\mathbb{R}$ . It is denoted by  $P_a A$  and it is a subset of  $T_a \mathbb{R}^n$ .

The following inclusions are always satisfied

$$C_a A \subset \tilde{C}_a A \subset P_a A.$$

Let us give an example of a contingent and paratangent cone at a point where  $A$  has an angle.

In the three last subsections of this survey, we will try to explain some relations between the Green bundles and these tangent cones. Unfortunately, in some cases, we need to use some modified Green bundles. Let us explain this. We use the constant  $c_0 = \frac{\sqrt{13}}{3} - \frac{5}{6}$ . We identify  $T_x(T^*M)$  to  $\mathbb{R}^n \times \mathbb{R}^n$  in such a way that  $\{0\} \times \mathbb{R}^n = V(x)$  is the vertical subspace and  $\mathbb{R}^n \times \{0\}$  is the horizontal subspace  $\mathcal{H}$ .

DEFINITION. We denote by  $S_{\pm}(x) : \mathbb{R}^n \rightarrow \mathbb{R}^n$  the linear operator such that  $G_{\pm}(x)$  is the graph of  $S_{\pm}(x)$ :  $G_{\pm}(x) = \{(v, S_{\pm}(x)v); v \in \mathbb{R}^n\}$ . Then the *modified Green bundles*  $\tilde{G}_{\pm}$  are defined by:

$$\tilde{G}_-(x) = \{(v, (S_-(x) - c_0(S_+(x) - S_-(x)))v); v \in \mathbb{R}^n\}$$

and

$$\tilde{G}_+(x) = \{(v, (S_+(x) + c_0(S_+(x) - S_-(x)))v); v \in \mathbb{R}^n\}.$$

REMARKS. We have:

$$\tilde{G}_- \leq G_- \leq G_+ \leq \tilde{G}_+.$$

Moreover, only the two following cases are possible

- either  $\tilde{G}_-(x), G_-(x), G_+(x), \tilde{G}_+(x)$  are all distinct;
- or  $\tilde{G}_- = G_- = G_+ = \tilde{G}_+$ .

In general, the tangent cones are not Lagrangian subspaces (they are not subspaces and not isotropic). Because we need to compare them to Lagrangian subspaces, we give a definition:

DEFINITION. Let  $\mathcal{L}_- \leq \mathcal{L}_+$  be two Lagrangian subspaces of  $T_x(T^*M)$  that are transverse to the vertical. If  $v \in T_x(T^*M)$  is a vector, we say that  $v$  is between  $\mathcal{L}_-$  and  $\mathcal{L}_+$  and write  $\mathcal{L}_- \leq v \leq \mathcal{L}_+$  if there exists a third Lagrangian subspace in  $T_x(T^*M)$  such that:

- $v \in \mathcal{L}$ ;
- $\mathcal{L}_- \leq \mathcal{L} \leq \mathcal{L}_+$ .

A subset  $B$  of  $T_x(T^*M)$  is between  $\mathcal{L}_-$  and  $\mathcal{L}_+$  if  $\forall v \in B, \mathcal{L}_- \leq v \leq \mathcal{L}_+$ . Then we write  $\mathcal{L}_- \leq B \leq \mathcal{L}_+$ .

REMARKS. In the 2-dimensional case,  $v$  is between  $\mathcal{L}_-$  and  $\mathcal{L}_+$  if and only if the slope of the line generated by  $v$  is between the slopes of  $\mathcal{L}_-$  and  $\mathcal{L}_+$ . In higher dimension, it is more complicated.

DEFINITION.

- A subset  $A$  of  $\mathbb{R}^n \times \mathbb{R}^n$  is  $C^1$ -isotropic at some point  $a \in A$  if  $\tilde{C}_a A$  is contained in some Lagrangian subspace;
- a subset  $A$  of  $\mathbb{R}^n \times \mathbb{R}^n$  is  $C^1$ -regular at some point  $a \in A$  if  $P_a A$  is contained in some Lagrangian subspace.

Of course, the  $C^1$ -regularity of  $A$  at a point  $a$  implies the  $C^1$ -isotropy at the same point. But the converse implication is not true.

Observe that a  $C^1$  Lagrangian submanifold is always  $C^1$ -regular.

### 3.2 Case I: 2-dimensional symplectic twist maps

The results that we explain now for the symplectic twist maps of the 2-dimensional annulus are proved in [2].

**Theorem 4.** *Let  $A$  be an Aubry-Mather set of a symplectic twist map of the 2-dimensional annulus  $\mathbb{A}_1$ . Then we have*

$$\forall a \in A, G_-(a) \leq P_a A \leq G_+(a).$$

**Corollary 1.** *Let  $\mu$  be a minimizing ergodic measure of a symplectic twist map of the 2-dimensional annulus. If the Lyapunov exponents of  $\mu$  are zero, then the support  $\text{supp}(\mu)$  of  $\mu$  is  $C^1$ -regular  $\mu$ -almost everywhere.*

**Question 1.** *We don't know any example of such an invariant measure with zero Lyapunov exponents such that  $\text{supp}\mu$  is not  $C^1$  at every point of  $\text{supp}\mu$ .*

**Question 2.** *We don't know any example of such an invariant measure with non-zero Lyapunov exponents such that  $\text{supp}\mu$  is not uniformly hyperbolic.*

Moreover, the following result is also true.

**Proposition 2.** *Let  $\mu$  be a minimizing ergodic measure of a symplectic twist map of the 2-dimensional annulus that has an irrational rotation number. If the Lyapunov exponents of  $\mu$  are non-zero, then the support  $\text{supp}(\mu)$  of  $\mu$  is  $C^1$ -irregular  $\mu$ -almost everywhere.*

We have even

**Proposition 3.** *Let  $\mu$  be a minimizing ergodic measure of a symplectic twist map of the 2-dimensional annulus that has an irrational rotation number. If the support  $\text{supp}(\mu)$  of  $\mu$  is  $C^1$ -irregular everywhere, then  $\text{supp}\mu$  is uniformly hyperbolic.*

Hence the size of the Lyapunov exponents can be read on the shape of  $\text{supp}(\mu)$ . But how can we see in practice this irregularity? For example, if we want to “draw” (with a computer) our irregular (and hyperbolic) Aubry-Mather sets, we can use some sequences of minimizing periodic orbits. But if we look at the pictures of Aubry-Mather sets that exist, we see Cantor sets or curves, but we never see angles of the tangent spaces. That's why the following question was raised by X. Buff :

**Question 3.** *(X. Buff) Is it possible (for example by using minimizing periodic orbits) to draw some Aubry-Mather sets with “corners”?*

### 3.3 Case II: invariant Lagrangian graphs of Tonelli Hamiltonians

The proofs of the result we present in this section are given in [1]. We obtain a statement similar to theorem 4 and corollary 1 but no analogue to proposition 2. Indeed, let us consider the following example:  $(\psi_t)$  is a geodesic Anosov flow defined on the cotangent bundle  $T^*\mathcal{S}$  of a closed surface  $\mathcal{S}$ . Let  $\mathcal{N} = T_1^*\mathcal{S}$  be its unitary cotangent bundle, which is a 3-manifold invariant by  $(\psi_t)$ . Then a method due to Mañé (see [19]) allows us to define a Tonelli Hamiltonian  $H$  on  $T^*\mathcal{N}$  such that the restriction of its flow  $(\varphi_t)$  to the zero section  $\mathcal{N}$  is  $(\psi_t)$ : the Lagrangian  $L$  associated with  $H$  is defined by:  $L(q, v) = \frac{1}{2}\|\dot{\psi}(q) - v\|^2$  where  $\|\cdot\|$  is any Riemannian metric on  $\mathcal{N}$ . In this case, the zero section is very regular (even  $C^\infty$ ), but the Lyapunov exponents of every invariant measure with support in  $\mathcal{N}$  are non zero (except two, the one corresponding to the flow direction and the one corresponding to the energy direction). Hence, it may happen that some exponents are non zero and the support of the measure is very regular.

**Theorem 5.** *Let  $\mathcal{G}$  be a Lipschitz Lagrangian graph that is invariant by the flow of a Tonelli Hamiltonian  $H : T^*M \rightarrow \mathbb{R}$ . Then we have:*

$$\forall x \in \mathcal{G}, G_-(x) \leq P_x \mathcal{G} \leq G_+(x).$$

The following corollary is not proved in [1] but is an easy consequence of theorems 5 and 1.

**Corollary 2.** *Let  $\mu$  be a minimizing ergodic measure for a Tonelli Hamiltonian of  $T^*M$ . If the Lyapunov exponents of  $\mu$  are zero and if the support of  $\mu$  is a graph above the whole manifold  $M$ , then the support  $\text{supp}(\mu)$  of  $\mu$  is  $C^1$ -regular  $\mu$ -almost everywhere.*

**Question 4.** *We don't know any example where such a  $\mu$  has zero Lyapunov and its support is not  $C^1$  at at least one point.*

With the hypotheses of corollary 2, if we can be more precise for the restricted dynamics to  $\text{supp}(\mu)$ , we can improve the result in the following way.

**Proposition 4.** *Let  $\mathcal{G}$  be a Lipschitz Lagrangian graph that is invariant by the flow of a Tonelli Hamiltonian  $H : T^*\mathbb{T}^n \rightarrow \mathbb{R}$ . We assume that for some  $T > 0$ , the restricted time- $T$  map  $\varphi_{T|\mathcal{G}}$  is Lipschitz conjugated to some rotation of  $\mathbb{T}^n$ . Then  $\mathcal{G}$  is the graph of a  $C^1$  function.*

When  $\mu$  is a minimizing measure with a support smaller than a Lagrangian graph, we don't obtain such a result (even if we have the sentiment that it could be true). A fundamental tool to prove the previous results is the following proposition (that is proved in [1]).

**Proposition 5.** *Assume that the orbit of  $x \in T^*M$  is globally minimizing for the Tonelli Hamiltonian  $H : T^*M \rightarrow \mathbb{R}$  and that  $\mathcal{L} : \mathbb{R} \rightarrow T(T^*M)$  is such that*

- *every  $\mathcal{L}(t)$  is a Lagrangian subspace of  $T_{\varphi_t^H(x)}(T^*M)$  that is transverse to the vertical subbundle;*
- $\forall s, t \in \mathbb{R}, D\varphi_{t-s}^H \mathcal{L}(s) = \mathcal{L}(t)$ .

*Then we have  $\forall t \in \mathbb{R}, G_-(\varphi_t^H(x)) \leq \mathcal{L}(t) \leq G_+(\varphi_t^H(x))$ .*

Using proposition 5 at any point where the invariant Lagrangian graph  $\mathcal{G}$  is differentiable, we deduce a similar inequality for  $\mathcal{L}$  being the tangent subspace at such a point. Then using a limit (and the notion of Clarke subdifferential), we deduce theorem 5.

If we could obtain a result similar to proposition 5 for vectors (instead of Lagrangian subspaces), we could deduce a similar statement for all minimizing measures. Hence we raise the question

**Question 5.** *Let  $(\mathcal{D}_t)$  (with  $t$  in  $\mathbb{Z}$  or  $\mathbb{R}$ ) be a globally positive diffeomorphism or a Tonelli Hamiltonian flow. Assume that the orbit of  $x \in T^*M$  is globally minimizing and that the vector  $v \in T_x(T^*M)$  is such that:  $\forall t, D\varphi_t(v) \notin V(\mathcal{D}_t x)$ . Is it true that:*

$$G_-(x) \leq v \leq G_+(x)?$$

REMARKS. Without a lot of change, all the results of this subsection could be proved for any Lipschitz Lagrangian graph that is invariant by a globally positive diffeomorphism of  $\mathbb{T}^n \times \mathbb{R}^n$ .

### 3.4 Case III: Tonelli Hamiltonians and globally positive diffeomorphisms

The results contained in this subsection come from [3] and [5]. They use in a fundamental way a recent theory called the weak KAM theory that was developed by A. Fathi in [11] in the case of the Tonelli Hamiltonians and by E. Garibaldi & P. Thieullen in [13] in the case of the globally positive diffeomorphisms.

**Theorem 6.** *Let  $\mu$  be a minimizing measure for a Tonelli Hamiltonian of  $T^*M$ . Then*

$$\forall x \in \text{supp}\mu, \tilde{G}_-(x) \leq \tilde{C}_x(\text{supp}\mu) \leq \tilde{G}_+(x).$$

Hence, the more irregular  $\text{supp}\mu$  is, i.e. the bigger the limit contingent cone is, the more distant  $\tilde{G}_-$  and  $\tilde{G}_+$  (and thus  $G_-$  and  $G_+$  too) are from each other and the larger the positive Lyapunov exponents are.

**Corollary 3.** *Let  $H : T^*M \rightarrow \mathbb{R}$  be a Tonelli Hamiltonian and let  $\mu$  be an ergodic minimizing probability all of whose Lyapunov exponents are zero. Then, at  $\mu$ -almost every point of the support  $\text{supp}(\mu)$  of  $\mu$ , the set  $\text{supp}(\mu)$  is  $C^1$ -isotropic.*

There are two naturel questions, that are related to question 5 and that concern also the globally positive diffeomorphisms.

**Question 6.** *Can we replace  $\tilde{C}_x(\text{supp}\mu)$  by  $P_x(\text{supp}\mu)$  in theorem 6 and theorem 7?*

**Question 7.** *Can we replace  $\tilde{G}_\pm(x)$  by  $G_\pm(x)$  in theorem 6 and theorem 7?*

If the answer to question 6 is positive, we can replace “ $C^1$ -isotropic” by “ $C^1$ -regular” in corollary 3 and corollary 4.

For the globally positive diffeomorphisms, we obtain a result only for the so-called strongly minimizing measures (the point is that for Tonelli Hamiltonians, minimizing measures are also strongly minimizing).

**DEFINITION.** Let  $F$  be a lift of a *globally positive* diffeomorphism  $f$  with generating function  $S : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ . A invariant Borel probability  $\nu$  on  $\mathbb{T}^n \times \mathbb{T}^n$  is *strongly minimizing* if  $\nu$  is a minimizer in the following formula

$$\inf_{\mu} \int_{\mathbb{R}^n \times \mathbb{R}^n} S(x, y) d\tilde{\mu}(x, y);$$

where the infimum is taken on the set of the Borel probability measures that are invariant by  $f$  and  $\tilde{\mu}$  is any lift of  $\mu$  to a fundamental domain of  $\mathbb{R}^n \times \mathbb{R}^n$  for the projection  $(x, y) \mapsto (x, -\frac{\partial S}{\partial x}(x, y))$  onto  $\mathbb{T}^n \times \mathbb{R}^n$ .

E. Garibaldi & P. Thiullen proved in [13] that such strongly minimizing measures exist. Moreover, they are minimizing.

**Theorem 7.** *Let  $\mu$  be a strongly minimizing measure of a globally positive diffeomorphism of  $\mathbb{A}_n$  et let  $\text{supp}\mu$  be its support. Then*

$$\forall x \in \text{supp}\mu, \tilde{G}_-(x) \leq \tilde{C}_x(\text{supp}\mu) \leq \tilde{G}_+(x).$$

**Corollary 4.** *Let  $\mu$  be an ergodic strongly minimizing measure of a globally positive diffeomorphism of  $\mathbb{A}_n$  all exponents of whose are zero. Then  $\text{supp}\mu$  is  $C^1$ -isotropic almost everywhere.*
